#### 1 Data from list plugin

### 1 Introduction

With the "Data from list" data filtration plugin you can quickly replace the current value of a variable with one from a list. For instance, you can replace an error code with its human-comprehensible textual description without having to leverage additional modules like "Expressions" or "Script Execute."

# 2 System requirements

The following requirements must be met for "Data from list" to be installed:

**Operating system**: Windows 2000 SP4 and above, including both x86 and x64 workstations and servers. The latest service pack for the corresponding OS is required.

Free disk space: Not less than 5 MB of free disk space is recommended.

**Special access requirements**: You should log on as a user with Administrator rights in order to install this module.

The main application (core) must be installed, for example, Advanced Serial Data Logger.

# 3 Installing Data from list

- 1. Close the main application (for example, Advanced Serial Data Logger) if it is running;
- 2. Copy the program to your hard drive;
- 3. Run the module installation file with a double click on the file name in Windows Explorer;
- Follow the instructions of the installation software. Usually, it is enough just to click the "Next" button several times;
- 5. Start the main application. The name of the module will appear on the "Modules" tab of the "Settings" window if it is successfully installed.

If the module is compatible with the program, its name and version will be displayed in the module list. You can see examples of installed modules on fig.1-2. Some types of modules require additional configuration. To do it, just select a module from the list and click the "Setup" button next to the list. The configuration of the module is described below.

You can see some types of modules on the "Log file" tab. To configure such a module, you should select it from the "File type" list and click the "Advanced" button.

2

Configuration		?	×				
COM port	Query Parse Filter						
Log file	Data query module						
Other	None	$\sim$	S	etup			
Modules	Parser module						
Query Parse   ASCII data query and parser (default.dll)   Setup     Query Parse   Parsing and exporting for data sent     Parsing and exporting for data received     Select data filter modules							
Data export	Module name Data From List (datafromlist.dll)	Version 4.0.16.720					
Events handling				2			
	Up Down Hel	p	S	etup			
	40	<	Ca	ancel

## 4 Glossary

**Main program** - it is the main executable of the application, for example, Advanced Serial Data Logger and asdlog.exe. It allows you to create several configurations with different settings and use different plugins.

**Plugin** - it is the additional plugin module for the main program. The plugin module extends the functionality of the main program.

**Parser** - it is the plugin module that processes the data flow, singling out data packets from it, and then variables from data packets. These variables are used in data export modules after that.

Core - see "Main program."

# 5 Configuration

The configuration of the "Data from list" module is very simple (Fig.1) and consists of just a handful of options.

Data From List 4.0.16.720 ?   This plugin gets a value of parser item and searches for a new value in the specified list   Example: OldValue1=NewValue1;OldValue2=NewValue2;OldValueN=NewValueN	×								
This plugin gets a value of parser item and searches for a new value in the specified list Example: OldValue1=NewValue1;OldValue2=NewValue2;OldValueN=NewValueN									
Example: OldValue1=NewValue1;OldValue2=NewValue2;OldValueN=NewValueN									
	Example: 0IdValue1=NewValue1;0IdValue2=NewValue2;0IdValueN=NewValueN								
You may specify a text file name with your list (one pair per line)									
Variables									
Source Destination List									
VAL1 VAL1 e:\list.txt									
VAL2 VAL2 NEW_VAR value1=1;value2=2;value3=3	3								
Set value to NULL if not found in a list									
OK Cancel									

Fig.1. Configuration window

**Variables** – in this group of settings, select or enter the variable name in the first column. Then specify the replacement list or the path to a text file with the list in the "List" column. If you specify a file name, the program automatically checks whether the file has been updated and, if so, reloads the list to the memory all over. If the "Destination" column is not empty, it contains the name of a destination variable with a decoded value.

Example of a list stored in a text file:

value1=1 value2=2 value3=3

**Set value to NULL** – when the option is enabled, and the source value does not exist in the list, the program will reset (clear) the value of the variable. Otherwise, it will keep the original value.

When a new packet of data with variables is received, the program compares the current value of the specified variable with the first value of each list item (value1, value2, value3, etc. in the example) and, if the match is found, replaces the value of the variable with the second value of the list item (1, 2, or 3 respectively).
